ABSTRACT

BACKGROUND

This study aimed to investigate the positional changes of the hyoid bone following orthognathic surgery in skeletal class III patients.

METHODS

This double-blinded quasi-experimental study was carried out in Mashhad University of Medical Sciences, Iran, from Apr 2019 to Jun 2020. All skeletal Class III patients who were candidates for orthogenetic surgery were included. They underwent mandibular setback surgery using bilateral sagittal split osteotomy. Cephalometric assessments in relation to hyoid bone position and posterior airway space (PAS) were conducted one day preoperatively (T0), as well as one week (T1), six months (T2) and one year (T3) postoperatively, determining the parameters like the Long axis of the hyoid bone (LAH), Retrognathion (RGn), Hyoidale (H), Palatal plane (PP), Mandibular plane (MP) and C3 Vertebrae (C3). All cephalograms were examined using AudaxCeph, Planmeca software. The data analysis was performed via SPSS-19 ($P<0.05$)

RESULTS

25 class III patients, including 18 females (72%) and 7 males (28%) with a mean age of 24.32 ± 5.87 , were studied. The cephalometric analysis demonstrated significant decreases in variable angles during the follow-up periods, except for LAH-MP angle ($P<0.001$). The hyoid bone moved downward and backward relative to its original position following the mandibular setback surgery. However, the bone gradually returned to the preoperative location between 6 to 12 months postoperatively.

CONCLUSION

The findings revealed the downward and backward movement of the hyoid bone following the mandibular setback surgery, returned near to its preoperative position after 1 year, postoperatively.

KEYWORDS

Orthognathic surgery; Hyoid bone; Cephalometric analysis

INTRODUCTION

Orthognathic surgery for skeletal malformation is the distinguished care and practice for enhancing facial esthetics, dental occlusion, and maxillomandibular relations¹⁻³. However, the review of the literature suggested a possible association between the orthognathic surgeries and changes in posterior airway space (PAS)^{4,7}. The soft palate, tongue, and hyoid bone are attached directly or indirectly to the maxilla and mandible. Therefore, the above-mentioned structures are directly affected by the jaw movement, causing alterations in the pharyngeal area^{4, 6-11}.

Mandibular setback surgery with or without maxillary advancement is a common treatment plan in patients with skeletal class III malocclusion^{1, 3, 12, 13}.

Mandibular displacement during orthognathic surgery may affect the positioning of the hyoid bone and tongue and therefore contribute to narrowing of the airway and development of obstructive sleep apnea^{3, 12-18}.

The hyoid bone is an important part of the cranio-maxillofacial complex^{4, 6-11}. The position of the hyoid bone is affected by the supra- and infrahyoid muscles, and by the elastic membranes of the larynx and the trachea^{6, 13, 19, 20}. The alterations in mandibular position are related to the hyoid bone changes^{4-11, 13, 15, 18-21}. Moreover, the hyoid bone position adapts to anteroposterior changes in head posture^{6, 13, 19, 20}. Thus, evaluation of the hyoid bone positional changes after mandibular setback surgery in patients with Class III deformity is mandatory.

Lateral cephalometric radiography remains an important imaging tool in orthognathic surgical planning^{6, 9, 10, 14, 22-24}. It allows the maxillofacial surgeon to plan the surgery and jaw movements, as well as collect relevant information about the hard and soft tissue structures and airway space^{6, 17}. Even though this radiographic imaging provides only two-dimensional images for the evaluation of the pharyngeal airway and hyoid bone, it is still used to evaluate sleep disorders and skeletal deformities^{6, 9, 10, 14, 22-24}.

To the best of our knowledge, few studies investigated the long-term changes in hyoid bone position following orthognathic surgery^{6-9, 19, 21}. However, the long-term effect of mandibular setback surgery on the hyoid bone movement is still a controversial topic^{2, 6-9, 11, 19, 21}. Hence, regarding the influence of the hyoid bone position on the posterior airway space (PAS), the aim of this study was to investigate the positional changes of hyoid bone following orthognathic surgery in skeletal class III patients for a 12-month follow-up period in the Iranian population, using lateral cephalometric analysis.

MATERIALS AND METHODS

Study design and patient selection

This before-after double-blinded quasi-experimental study was performed in Ghaem Hospital, and the Oral and Maxillofacial Surgery Department of Mashhad Dental School, Mashhad University of Medical Sciences, Mashhad, Iran, from Apr 2019 to Jun 2020.

The inclusion criteria were all the healthy patients who were candidates to treat class III malocclusion. Participants were both male and female, aged from 18 to 40 yr old who were ASA I, II regarding systematic conditions. Patients suffering from respiratory and airway problems were excluded as well as those who were not willing to continue participation or follow-ups.

This experiment consisted of two groups. Setback surgery of mandible (BSSO-Bilateral Sagittal Split Osteotomy technique) was performed in one group (Monomax surgery) and in another group, bimaxillary orthognathic operations (Bimax) including maxillary advancement (LeFort I) plus mandibular setback (BSSO) were done.

The need for mandibular setback plus maxillary advancement was established by clinical and cephalometric examinations in our cases.

All orthognathic surgeries were conducted by the same surgeon and the same surgical team and hospital. For general hypotensive anesthesia, all patients were given the same standard intravenous drug regimens.

Patients underwent mandibular setback surgery (BSSO) with or without maxillary advancement (LeFort I). The rigid fixation of the maxillomandibular segments was performed.

Variables and Data collection

Age, gender, date, and type of surgery as well as the amount of maxillomandibular displacement were recorded. The change in the position of the hyoid bone was the primary outcome variable in the present study.

All the patients with Cl III malocclusion who were eligible to enter the study were asked to complete a demographic questionnaire and take a lateral cephalogram one day before the surgery (T0) at Ghaem Hospital. Then positional evaluations of hyoid bone were performed based on the radiographs.

The dependent variables were as follows the Long axis of the hyoid bone (LAH), Retrognation (RGn), Hyoidale (H), Palatal plane (PP), Mandibular plane (MP), and C3 Vertebrae (C3). Postoperative radiographic analyses were done 1 week (T1), six months (T2), and one year (T3) later to reevaluate the position of hyoid bone. All cephalograms were analyzed using AudaxCeph, Planmeca software (Planmeca, Helsinki, Finland).

The best approach for this investigation was to use anatomical landmarks adopted from Mortazavi et al.⁶ survey. The use of these landmarks enabled us to evaluate the position of hyoid bone in two dimensions and the sagittal plane comprehensively (Figure 1).

Fig. 1: Lateral cephalometric analysis of patient with traced hyoid landmarks: (A) before the surgery (T0) and (B) after 1 year of follow up (T3).

Several parameters were measured in all patients, including the distance between H and MP, H and PP, H and C3, H and RGn as well as angulation between LAH and MP and also between LAH and PP. Other variables are the type of deformity, age, gender, movement of the jaw due to surgery, and the number of jaws involved.

Both the statistical and cephalometric analyst were unaware of the surgical procedure as well as the amount of maxillomandibular displacement (in millimeters). However, the surgeon and the student who had completed the checklist were aware of the surgery.

Statistical analyses

Collected data analysis was carried out via repeated measures ANOVA test and SPSS version 19 (SPSS Inc., Chicago, IL). Qualitative variables were expressed as a percentage, while quantitative variables were stated as mean \pm SD (standard deviation). *P*-value less than 0.05% was considered significant.

Ethical Approval

All procedures performed in this study involving the human participant were in accordance with the ethical standards of our institutional Research Committee and with the 1964 Helsinki declaration. The patient's ethical consent form was signed and approved by the patient. All procedures used in this research were approved by the Ethical Committee of Mashhad University of Medical Sciences (IR.MUMS.DENTISTRY.REC.1398.104).

RESULTS

There were 25 participants, including 18 females (72%) and seven males (28%) aged from 18 to 37 and with a mean age of 24.32 ± 5.87 . One group ($n=7$) underwent Monomax, and the other group ($n=18$) treated by the Bimax technique.

Amounts of jaw displacement during the orthognathic surgeries were calculated. The mean amount of the mandibular setback in patients was 5.24 ± 1.48 mm.

The mean of mandibular setback displacement for the group in which the monomax (isolated mandibular setback) surgery was performed, was considerably more than the bimaxillary operated samples ($P<0.001$) (Table 1). Table 2 indicated no significant association between the hyoid parameter alterations and age, mandibular seatback or maxillary advancement.

With respect to comparison between monomaxillary and bimaxillary surgeries, the mean changes regarding angulation of LAH_PP, LAH_MP and mean changes of H_PP distance as well as H_RGn distance in bimaxillary surgeries were less than monomax, with no significant differences ($P=0.495$, $P=0.547$, $P=0.790$ and $P=0.498$, respectively). In fact, the average of changes in H_MP and H_C3 distance were more in the bimaxillary surgeries compared to isolated mandibular setback operations (Table 3).

Moreover, the average of changes regarding H_PP, H_MP, H_RGn and LAH_PP in the males was less than the females, with no significant difference (Table 4).

Table 1: Mandibular displacement amounts in Monomaxillary and Bimaxillary surgery

Surgery	Number (N)	Mean± SD	Median	Independent <i>t</i> test
Monomaxillary	7	7.14±0.900	7.00	Z=3.79
Bimaxillary	18	4.50±0.857	4.50	P<0.001

Table 2: The correlation between hyoid variables and age, mandibular setback and maxillary advancement amount

Variables (parameters)		Age (N=25)	Amount of Mandibular setback (N=25)	Amount of Maxillary advancement (N=18)
H_PP Distance	Spearman's correlation coefficient	0.046	0.219	0.158
	P-value	0.828	0.293	0.531

	Bimaxillary	18	-48.42±99.69	-14.14	P=0.574

Z: Mann Whitney Test
T: T-test

Nevertheless, the average of LAH_MP angulation changes in the males was significantly more than females ($P=0.027$) (Table 4).

Comparison of the hyoid variables during the time intervals of follow-ups demonstrated the significant changes in parameters after the orthognathic surgery except for LAH_MP ($P<0.001$) (Table 5).

The mean distance of H_PP at T1 was significantly higher than at other time intervals ($P<0.001$) and at T2 was significantly higher than T0, as well ($P<0.001$). The

mean H-MP, H-C3, and the mean distance of H_RGn were significantly decreased at all-time intervals compared to T0 ($P<0.001$). Moreover, these parameters were significantly reduced at T3 compared to T1 ($P<0.001$). The mean angle of LAH_PP at T1 was significantly lower than T0. In addition, the mean angle of LAH_PP at T3 was significantly less than T1 and T2 ($P<0.001$). There was no significant difference between other two-pair comparisons for any of the variables (Table 5).

Table 4: Comparison of hyoid parameters between the males and females

Variables (Parameters)	Gender	Number (N)	Mean \pm SD	Independent T Test
H_PP Distance	Female	18	0.46 \pm 5.00	T=1.33
	Male	7	-2.12 \pm 1.50	P=0.061
H_MP Distance	Female	18	23.74 \pm 11.76	T=0.50
	Male	7	20.42 \pm 21.48	P=0.622
H_C3 Distance	Female	18	0.38 \pm 3.51	T=1.82
	Male	7	3.35 \pm 4.07	P=0.082
H_RGn Distance	Female	18	12.38 \pm 4.71	T=0.87
	Male	7	10.39 \pm 6.24	P=0.395
LAH_PP Angle	Female	18	-0.92 \pm 11.39	T=1.56
	Male	7	-10.93 \pm 20.74	P=0.133
LAH_MP Angle	Female	18	-60.32 \pm 109.77	T=1.59
	Male	7	7.82 \pm 33.84	P=0.027*

*: Significant difference.

DISCUSSION

Our study findings revealed the downward and backward movement of the hyoid bone following the mandibular setback surgery, returned near to its pre-operative position after one year, postoperatively.

Few researchers have studied the alterations in the position of hyoid bone due to orthognathic surgeries and there are still some controversies within the literature concerning this issue^{2, 6-9, 11, 19, 21}. Regarding the published articles, after mandibular setback surgery the hyoid bone may move inferiorly, both inferiorly and posteriorly, and both inferiorly and forward^{7-9, 11, 15, 17-21, 24, 25}. The hyoid bone returns to its original position, maintaining the airway resistance^{4, 6, 7, 12, 19, 26}. These changes can occur because of the physiologic reflex mechanism for maintaining the posterior airway space^{4, 6, 7, 12}.

In orthognathic surgeries, the hyoid bone acts as a reference for measuring and evaluating the position of the mandible and maxilla^{6, 13, 19, 20}. The hyoid bone is considered as the base of the tongue due to the close relationship between these structures^{6, 13, 19, 20}. Therefore, the position of the hyoid bone plays a crucial role in obtaining the posterior airway space. The mandibular setback surgery (BSSO) involves the changes regarding the hyoid position and as a result, affects the posterior airway space^{4-11, 13, 15, 18-21}. Mandibular displacement during orthognathic surgery may affect the positioning of the hyoid bone and tongue and therefore contribute to narrowing of the airway and development of obstructive sleep apnea^{6, 13, 19, 20}.

Cephalometric assessments are valuable for determination of the hyoid bone position and posterior airway space (PAS) due to recent studies^{2, 6-9, 11, 19, 21}.

Table 5: The changes of hyoid parameters following the orthognathic surgery in different time intervals

Variables (Parameters)	Intervals	Number (N)	MEAN *± SD	Repeated Measures ANOVA Test
H_PP Distance	T0	25	56.70 ^a ±6.65	<i>P</i> <0.001*

	T3	25	25.88 ^c ±8.58	
LAH_MP Angle	T0	25	4.64±5.59	<i>P</i> =0.228
	T1	25	5.66±5.33	
	T2	25	5.46±5.46	
	T3	25	5.68±4.65	

T0: one day before the surgery.

T1: 1 week, T2: six months, and T3: one year postoperatively.

*: Significant difference.

The superscript letters had significant relations.

The hyoid bone moves downward and backward relative to the previous position following the mandibular setback surgery. Similarly, back and downward reposition were reported^{15,21}, whereas no significant change in the location of the hyoid bone was observed in other studies^{19,26}.

In contrast to our findings, Tselnik et al reported forward and downward movement of hyoid bone immediately after the setback surgery²⁷, which may be due to different criteria of measurement and the effect of

maxillary impaction on the occlusal plane and hyoid plane alteration, consequently^{1,6}.

Accordingly, an upward movement of hyoid bone was reported following the bimaxillary surgery²⁰. Moving toward upper position is a physiological adaptation to sustain the airway opening. The controversies regarding the results of previous studies may be due to the difference in sample sizes, cephalometric analysis parameters, and simultaneous maxillary vertical plane movements in these studies^{1,4,6,17}.

Furthermore, in our study, the hyoid bone gradually returned to the preoperative position in 6 to 12 months follow-up intervals, observed in both Monomax and Bimax surgeries. This finding was consistent with the prior study results^{3, 6, 8, 9, 19, 21}. As proposed, a study of 46 Cl III samples was performed, of which 25 participants underwent the bilateral sagittal split osteotomy (BSSO), and 21 subjects received bilateral intraoral vertical ramus osteotomy (IVRO)¹⁰. The hyoid bone showed a tendency to return to its original place, however, the posterior airway space remains narrow during the follow-up period¹⁰.

The sample size of the present study was similar to Efendiyeva et al.²⁰, and Kim et al.²⁸ study (25 participants), whereas this study included more subjects than Liukkonen et al.²⁶ and Foltan et al.¹⁵, which were 22 and 21 patients, respectively.

The findings of the present study demonstrated no difference related to gender in positional changes of hyoid bone which implied the similar adaptation process of hyoid in male and female patients after the jaw movements in orthognathic surgery. Our result was in line with most of the studies^{3, 6, 8, 9, 19, 21}. Nonetheless, the hyoid repositioning happened only in females and reported no significant movement in males¹⁷.

Despite the movement of the hyoid bone toward the previous position between 6 to 12 months after the operation, it probably might never reach to its former exact location^{6, 7, 9, 11, 26}, which may result in the posterior airway space reduction and post-operative obstructive sleep apnea^{1, 3, 6, 7, 9, 11, 26}, the bimaxillary surgery was preferred rather than the isolated mandibular setback in the case of skeletal cl III deformity to prevent probable PAS reduction¹⁴.

A remarkable feature of this study was its one-year follow-up period which is the same as other studies^{8, 9, 19, 21}. Long-term follow-up allowed us to assure the patients of the impermanency of probable postoperative mentioned complications. Nonetheless, the follow up durations of various studies by^{15, 18, 28} were shorter than the current study.

CONCLUSION

This study findings revealed the downward and backward movement of the hyoid bone following the mandibular setback surgery, returned near to its normal position after one year, postoperatively. Since fewer changes were observed in the patients underwent Bimax, the bimaxillary surgeries might be advantageous to maintain PAS in cases who required large amounts of mandibular setback reposition.

LIMITATIONS

With respect to the sample size of similar research and the pilot status of this study, one limitation of our implementation is the small sample size. Due to the COVID-19 pandemic in the world and Iran and quarantine protocols, it was not possible to follow up more patients. However, the present study statistical results were satisfactory. Future surveys involving a larger sample size are suggested.
